

# Physics 4.3 Particle model of matter

<p><b>4.3.1</b></p>	<p><b>Changes of state and the particle model</b></p>
<p><b>4.3.1.1</b> <b>Density of materials</b></p> 	<p>The density of a material is defined by the equation:  <math display="block">\text{density} = \frac{\text{mass}}{\text{volume}} \quad \rho = \frac{m}{V}</math></p> <p>density, <math>\rho</math>, in kilograms per metre cubed, <math>\text{kg/m}^3</math> mass, <math>m</math>, in kilograms, <math>\text{kg}</math> volume, <math>V</math>, in metres cubed, <math>\text{m}^3</math></p> <p>The particle model can be used to explain</p> <ul style="list-style-type: none"> <li>the different <b>states of matter – solids, liquids and gases</b></li> <li>differences in density – solids are more dense as particles are closely packed together</li> </ul> <p>Required practical - calculate density</p>
<p><b>4.3.1.2</b> <b>Change of state</b></p>	<p>When substances <b>change state (melt, freeze, boil, evaporate, condense or sublimate)</b>, mass is conserved.</p>  <p>Changes of state are physical changes which differ from chemical changes because the material recovers its original properties if the change is reversed.</p>
<p><b>4.3.2</b></p>	<p><b>Internal energy and energy transfers</b></p>
<p><b>4.3.2.1</b> <b>Internal energy</b></p>	<p>Energy is <b>stored inside a system</b> by the particles (atoms and molecules) that make up the system. This is called <b>internal energy</b>.</p> <p><b>Internal energy</b> is the total <b>kinetic energy</b> and <b>potential energy</b> of <b>all the particles</b> (atoms and molecules) that make up a system.</p> <p><b>Heating changes</b> the <b>energy stored</b> within the system by <b>increasing the energy of the particles</b> that make up the system. This either <b>raises the temperature</b> of the system or produces a <b>change of state</b>.</p>
<p><b>4.3.2.2</b> <b>Temperature changes in a system and specific heat capacity</b></p>	<p>If the temperature of the system increases, the increase in temperature depends on the mass of the substance heated, the type of material and the energy input to the system.</p> <p>You need to use the following equation:  <math display="block">\text{change in thermal energy} = \text{mass} \times \text{specific heat capacity} \times \text{temperature change}</math> <math display="block">\Delta E = m c \Delta \theta</math></p> <p>change in thermal energy, <math>\Delta E</math>, in joules, <math>\text{J}</math> mass, <math>m</math>, in kilograms, <math>\text{kg}</math>          specific heat capacity, <math>c</math>, in joules per kilogram per degree Celsius, <math>\text{J/kg } ^\circ\text{C}</math>          temperature change, <math>\Delta \theta</math>, in degrees Celsius, <math>^\circ\text{C}</math>.</p> <p>The <b>specific heat capacity</b> of a substance is the <b>amount of energy</b> required to <b>raise the temperature</b> of <b>one kilogram</b> of the substance by <b>one degree Celsius</b>.</p>
<p><b>4.3.2.3</b> <b>changes of heat and specific latent heat</b></p>	<p>If a change of state happens:</p> <p>The <b>energy needed for a substance to change state</b> is called <b>latent heat</b>. When a change of state occurs, the energy supplied changes the energy stored (internal energy) but not the temperature.</p> <p>The <b>specific latent heat</b> of a substance is the amount of energy required to <b>change the state of one kilogram</b> of the substance with no change in temperature</p>

	<p><b>energy for a change of state = mass × specific latent heat</b></p> <p><b><math>E = m L</math></b></p> <p>energy, <math>E</math>, in joules, J    mass, <math>m</math>, in kilograms, kg  specific latent heat, <math>L</math>, in joules per kilogram, J/kg</p> <p>Specific latent heat of <b>fusion</b> – change of state from <b>solid to liquid</b></p> <p>Specific latent heat of <b>vaporisation</b> – change of state from <b>liquid to vapour</b></p>
<p><b>4.3.3</b></p>	<p><b>Particle model and pressure</b></p>
<p><b>4.3.3.1</b>  <b>Particle motion</b>  <b>in gases</b></p>	<p>The molecules of a gas are in constant random motion. The temperature of the gas is related to the average kinetic energy of the molecules.</p> <p>Changing the temperature of a gas, held at constant volume changes the pressure exerted by the gas. Increasing temperature increases pressure.</p>
<p><b>4.3.3.2</b>  <b>Pressure in gases</b>  <b>(physics only)</b></p> 	<p>A gas can be compressed or expanded by pressure changes. The pressure produces a net force at right angles to the wall of the gas container (or any surface). Increasing the volume in which a gas is contained, at constant temperature, can lead to a decrease in pressure</p> <p>For a fixed mass of gas held at a constant temperature:</p> <p><b><math>pressure \times volume = constant</math></b></p> <p><b><math>p V = constant</math></b></p> <p>pressure, <math>p</math>, in pascals, Pa    volume, <math>V</math>, in metres cubed, <math>m^3</math></p>
<p><b>4.3.3.3 increasing</b>  <b>the pressure of a</b>  <b>gas (physics HT</b>  <b>only)</b></p>	<p>Work is the transfer of energy by a force. Doing work on a gas increases the internal energy of the gas and can cause an increase in the temperature of the gas e.g. Using a bicycle pump, doing work on an enclosed gas leads to an increase in the temperature of the gas, because the pressure is increased.</p>
